

NAME

chown, fchown, lchown, fchownat – change ownership of a file

LIBRARY

Standard C library (*libc*, *-lc*)

SYNOPSIS

```
#include <unistd.h>

int chown(const char *pathname, uid_t owner, gid_t group);
int fchown(int fd, uid_t owner, gid_t group);
int lchown(const char *pathname, uid_t owner, gid_t group);

#include <fcntl.h>      /* Definition of AT_* constants */
#include <unistd.h>

int fchownat(int dirfd, const char *pathname,
             uid_t owner, gid_t group, int flags);
```

Feature Test Macro Requirements for glibc (see **feature_test_macros(7)**):

```
fchown(), lchown():
/* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L
|| _XOPEN_SOURCE >= 500
|| /* glibc <= 2.19: */ _BSD_SOURCE

fchownat():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_ATFILE_SOURCE
```

DESCRIPTION

These system calls change the owner and group of a file. The **chown()**, **fchown()**, and **lchown()** system calls differ only in how the file is specified:

- **chown()** changes the ownership of the file specified by *pathname*, which is dereferenced if it is a symbolic link.
- **fchown()** changes the ownership of the file referred to by the open file descriptor *fd*.
- **lchown()** is like **chown()**, but does not dereference symbolic links.

Only a privileged process (Linux: one with the **CAP_CHOWN** capability) may change the owner of a file. The owner of a file may change the group of the file to any group of which that owner is a member. A privileged process (Linux: with **CAP_CHOWN**) may change the group arbitrarily.

If the *owner* or *group* is specified as *-1*, then that ID is not changed.

When the owner or group of an executable file is changed by an unprivileged user, the **S_ISUID** and **S_ISGID** mode bits are cleared. POSIX does not specify whether this also should happen when root does the **chown()**; the Linux behavior depends on the kernel version, and since Linux 2.2.13, root is treated like other users. In case of a non-group-executable file (i.e., one for which the **S_IXGRP** bit is not set) the **S_ISGID** bit indicates mandatory locking, and is not cleared by a **chown()**.

When the owner or group of an executable file is changed (by any user), all capability sets for the file are cleared.

fchownat()

The **fchownat()** system call operates in exactly the same way as **chown()**, except for the differences described here.

If the *pathname* given in *pathname* is relative, then it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by **chown()** for a relative *pathname*).

If *pathname* is relative and *dirfd* is the special value **AT_FDCWD**, then *pathname* is interpreted relative to the current working directory of the calling process (like **chown()**).

If *pathname* is absolute, then *dirfd* is ignored.

The *flags* argument is a bit mask created by ORing together 0 or more of the following values;

AT_EMPTY_PATH (since Linux 2.6.39)

If *pathname* is an empty string, operate on the file referred to by *dirfd* (which may have been obtained using the **open(2)** **O_PATH** flag). In this case, *dirfd* can refer to any type of file, not just a directory. If *dirfd* is **AT_FDCWD**, the call operates on the current working directory. This flag is Linux-specific; define **_GNU_SOURCE** to obtain its definition.

AT_SYMLINK_NOFOLLOW

If *pathname* is a symbolic link, do not dereference it: instead operate on the link itself, like **lchown()**. (By default, **fchownat()** dereferences symbolic links, like **chown()**.)

See **openat(2)** for an explanation of the need for **fchownat()**.

RETURN VALUE

On success, zero is returned. On error, **-1** is returned, and *errno* is set to indicate the error.

ERRORS

Depending on the filesystem, errors other than those listed below can be returned.

The more general errors for **chown()** are listed below.

EACCES

Search permission is denied on a component of the path prefix. (See also **path_resolution(7)**.)

EBADF

(**fchown()**) *fd* is not a valid open file descriptor.

EBADF

(**fchownat()**) *pathname* is relative but *dirfd* is neither **AT_FDCWD** nor a valid file descriptor.

EFAULT

pathname points outside your accessible address space.

EINVAL

(**fchownat()**) Invalid flag specified in *flags*.

EIO

(**fchown()**) A low-level I/O error occurred while modifying the inode.

ELOOP

Too many symbolic links were encountered in resolving *pathname*.

ENAMETOOLONG

pathname is too long.

ENOENT

The file does not exist.

ENOMEM

Insufficient kernel memory was available.

ENOTDIR

A component of the path prefix is not a directory.

ENOTDIR

(**fchownat()**) *pathname* is relative and *dirfd* is a file descriptor referring to a file other than a directory.

EPERM

The calling process did not have the required permissions (see above) to change owner and/or group.

EPERM

The file is marked immutable or append-only. (See **ioctl_iflags(2)**.)

EROFS

The named file resides on a read-only filesystem.

VERSIONS

The 4.4BSD version can be used only by the superuser (that is, ordinary users cannot give away files).

STANDARDS

POSIX.1-2008.

HISTORY

chown()

fchown()

lchown()

4.4BSD, SVr4, POSIX.1-2001.

fchownat()

POSIX.1-2008. Linux 2.6.16, glibc 2.4.

NOTES**Ownership of new files**

When a new file is created (by, for example, **open(2)** or **mkdir(2)**), its owner is made the same as the filesystem user ID of the creating process. The group of the file depends on a range of factors, including the type of filesystem, the options used to mount the filesystem, and whether or not the set-group-ID mode bit is enabled on the parent directory. If the filesystem supports the **-o gr pid** (or, synonymously **-o bsd-groups**) and **-o nogrp id** (or, synonymously **-o sysvgroups**) **mount(8)** options, then the rules are as follows:

- If the filesystem is mounted with **-o gr pid**, then the group of a new file is made the same as that of the parent directory.
- If the filesystem is mounted with **-o nogrp id** and the set-group-ID bit is disabled on the parent directory, then the group of a new file is made the same as the process's filesystem GID.
- If the filesystem is mounted with **-o nogrp id** and the set-group-ID bit is enabled on the parent directory, then the group of a new file is made the same as that of the parent directory.

As at Linux 4.12, the **-o gr pid** and **-o nogrp id** mount options are supported by ext2, ext3, ext4, and XFS. Filesystems that don't support these mount options follow the **-o nogrp id** rules.

glibc notes

On older kernels where **fchownat()** is unavailable, the glibc wrapper function falls back to the use of **chown()** and **lchown()**. When *pathname* is a relative pathname, glibc constructs a pathname based on the symbolic link in */proc/self/fd* that corresponds to the *dirfd* argument.

NFS

The **chown()** semantics are deliberately violated on NFS filesystems which have UID mapping enabled. Additionally, the semantics of all system calls which access the file contents are violated, because **chown()** may cause immediate access revocation on already open files. Client side caching may lead to a delay between the time where ownership have been changed to allow access for a user and the time where the file can actually be accessed by the user on other clients.

Historical details

The original Linux **chown()**, **fchown()**, and **lchown()** system calls supported only 16-bit user and group IDs. Subsequently, Linux 2.4 added **chown32()**, **fchown32()**, and **lchown32()**, supporting 32-bit IDs. The glibc **chown()**, **fchown()**, and **lchown()** wrapper functions transparently deal with the variations across kernel versions.

Before Linux 2.1.81 (except 2.1.46), **chown()** did not follow symbolic links. Since Linux 2.1.81, **chown()** does follow symbolic links, and there is a new system call **lchown()** that does not follow symbolic links. Since Linux 2.1.86, this new call (that has the same semantics as the old **chown()**) has got the same syscall

number, and **chown()** got the newly introduced number.

EXAMPLES

The following program changes the ownership of the file named in its second command-line argument to the value specified in its first command-line argument. The new owner can be specified either as a numeric user ID, or as a username (which is converted to a user ID by using **getpwnam**(3) to perform a lookup in the system password file).

Program source

```
#include <pwd.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    char          *endptr;
    uid_t         uid;
    struct passwd  *pwd;

    if (argc != 3 || argv[1][0] == '\0') {
        fprintf(stderr, "%s <owner> <file>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    uid = strtol(argv[1], &endptr, 10); /* Allow a numeric string */

    if (*endptr != '\0') {              /* Was not pure numeric string */
        pwd = getpwnam(argv[1]);        /* Try getting UID for username */
        if (pwd == NULL) {
            perror("getpwnam");
            exit(EXIT_FAILURE);
        }

        uid = pwd->pw_uid;
    }

    if (chown(argv[2], uid, -1) == -1) {
        perror("chown");
        exit(EXIT_FAILURE);
    }

    exit(EXIT_SUCCESS);
}
```
