

NAME

open_how – how to open a pathname

LIBRARY

Linux kernel headers

SYNOPSIS

```
#include <linux/openat2.h>
```

```
struct open_how {
    u64  flags;    /* O_* flags */
    u64  mode;     /* Mode for O_{CREAT,TMPFILE} */
    u64  resolve;  /* RESOLVE_* flags */
    /* ... */
};
```

DESCRIPTION

Specifies how a pathname should be opened.

The fields are as follows:

- flags* This field specifies the file creation and file status flags to use when opening the file.
- mode* This field specifies the mode for the new file.
- resolve* This is a bit mask of flags that modify the way in which *all* components of a pathname will be resolved (see **path_resolution(7)** for background information).

VERSIONS

Extra fields may be appended to the structure, with a zero value in a new field resulting in the kernel behaving as though that extension field was not present. Therefore, a user *must* zero-fill this structure on initialization.

STANDARDS

Linux.
